

COMBINATORIAL TESTING

PETER GORM LARSEN
PROFESSOR
(PGL@ENG.AU.DK)

PLAN

- › Need for testing and verification
- › Combinatorial testing
- › Test example
- › Model checking
- › State space explosion

NEED FOR TESTING & VERIFICATION

- › The Ariane 5 rocket exploded on June 4, 1996, less than forty seconds after it was launched.
- › The investigation committee found a **software error** in the computer **responsible** to calculate movement.
- › An **exception** occurred when a large 64-bit floating point number was converted to a 16-bit integer.
- › This conversion was **not protected** by code for handling exceptions and caused the computer to fail, incorrect attitude data was transmitted.

NEED FOR TESTING & VERIFICATION

- › No longer feasible to **shut down** a malfunctioning system in order to restore it.
- › Systems need to be analyzed not only for compiling and static **errors**.
- › The principal validation methods for complex systems are simulation, **testing**, and verification (**model checking**, deduction).

NEED FOR TESTING & VERIFICATION

- › The analysis is **expensive** to be performed on the actual software.
- › Huge state space, **combinatorial explosion**
- › Combining different techniques to achieve V&V: Cheap to expensive (small hummer, big hummer)

TESTING

- › Testing involves making experiments **before** deploying the system in the field.
- › Can be performed on a **model** or the actual system
- › Typically **inject** signals/inputs at certain points in the system and observe the **resulting** signals/outputs at other points.
- › Testing is a **cost-efficient** way to find many errors
- › However, checking all potential executions and interleaving using testing is **rarely** possible.

COMBINATORIAL TESTING PERSPECTIVE

The screenshot displays the Overture Tools IDE interface. The main window is titled "/test1.vdmpp - Overture Tools" and contains a code editor with the following code:

```

23
24 operations
25
26 public Run: () ==> set of Plant`Period * Expert
27 Run() ==
28   let periods = plant.ExpertIsOnDuty(ex1),
29   expert = plant.ExpertToPage(a1,p1)
30   in
31   return mk_(periods,expert);
32
33 traces
34
35 AddingAndDeleting: let myex in set exs
36                     in
37                     let myex2 in set exs \ {myex}
38                     in
39                     let p in set ps
40                     in
41                     (plant.AddExpertToSchedule(p,myex);
42                     plant.AddExpertToSchedule(p,myex2);
43                     plant.RemoveExpertFromSchedule(p,myex);
44                     plant.RemoveExpertFromSchedule(p,myex2));
45

```

A callout box labeled "Regular expression" points to the line number 35 in the code editor.

The right-hand side of the IDE features a "CT Overview" panel. It displays a list of test cases with their results:

- Test 000001: ✓
- Test 000002: ✓
- Test 000003: ✗
- Test 000004: ✗
- Test 000005: ✓
- Test 000006: ✓
- Test 000007: ✓
- Test 000008: ✓
- Test 000009: ✓
- Test 000010: ✓
- Test 000011: ✗
- Test 000012: ✗
- Test 000013: ✓
- Test 000014: ✓
- Test 000015: ✓
- Test 000016: ✓

A callout box labeled "Overview of results" points to the CT Overview panel.

At the bottom of the IDE, there is a "CT Test Case result" panel. It displays a table with the following data:

Trace Test case	Result
plant.AddExpertToSchedule(mk_token("Tuesday day"), myex)	()
plant.AddExpertToSchedule(mk_token("Tuesday day"), myex2)	()
plant.RemoveExpertFromSchedule(mk_token("Tuesday day"), myex)	Error 4130: Instance invariant violated: inv_Plant in 'Plant' at line 6

A callout box labeled "Detailed test case and results" points to the CT Test Case result panel.

EXAMPLE

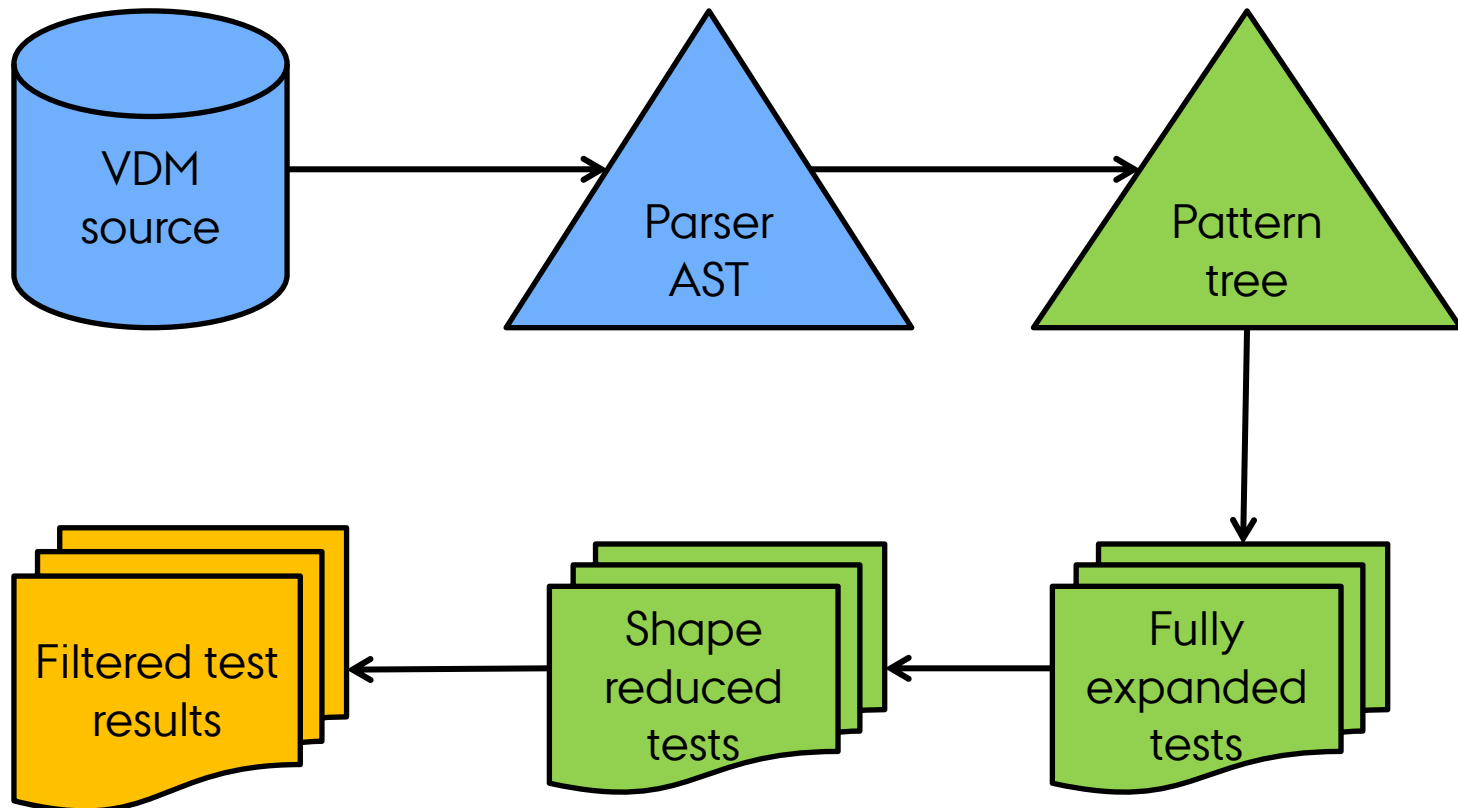

Trace:

```
TTest: (let x in set {1, 2}  
       in t.Insert(x)) {3}
```

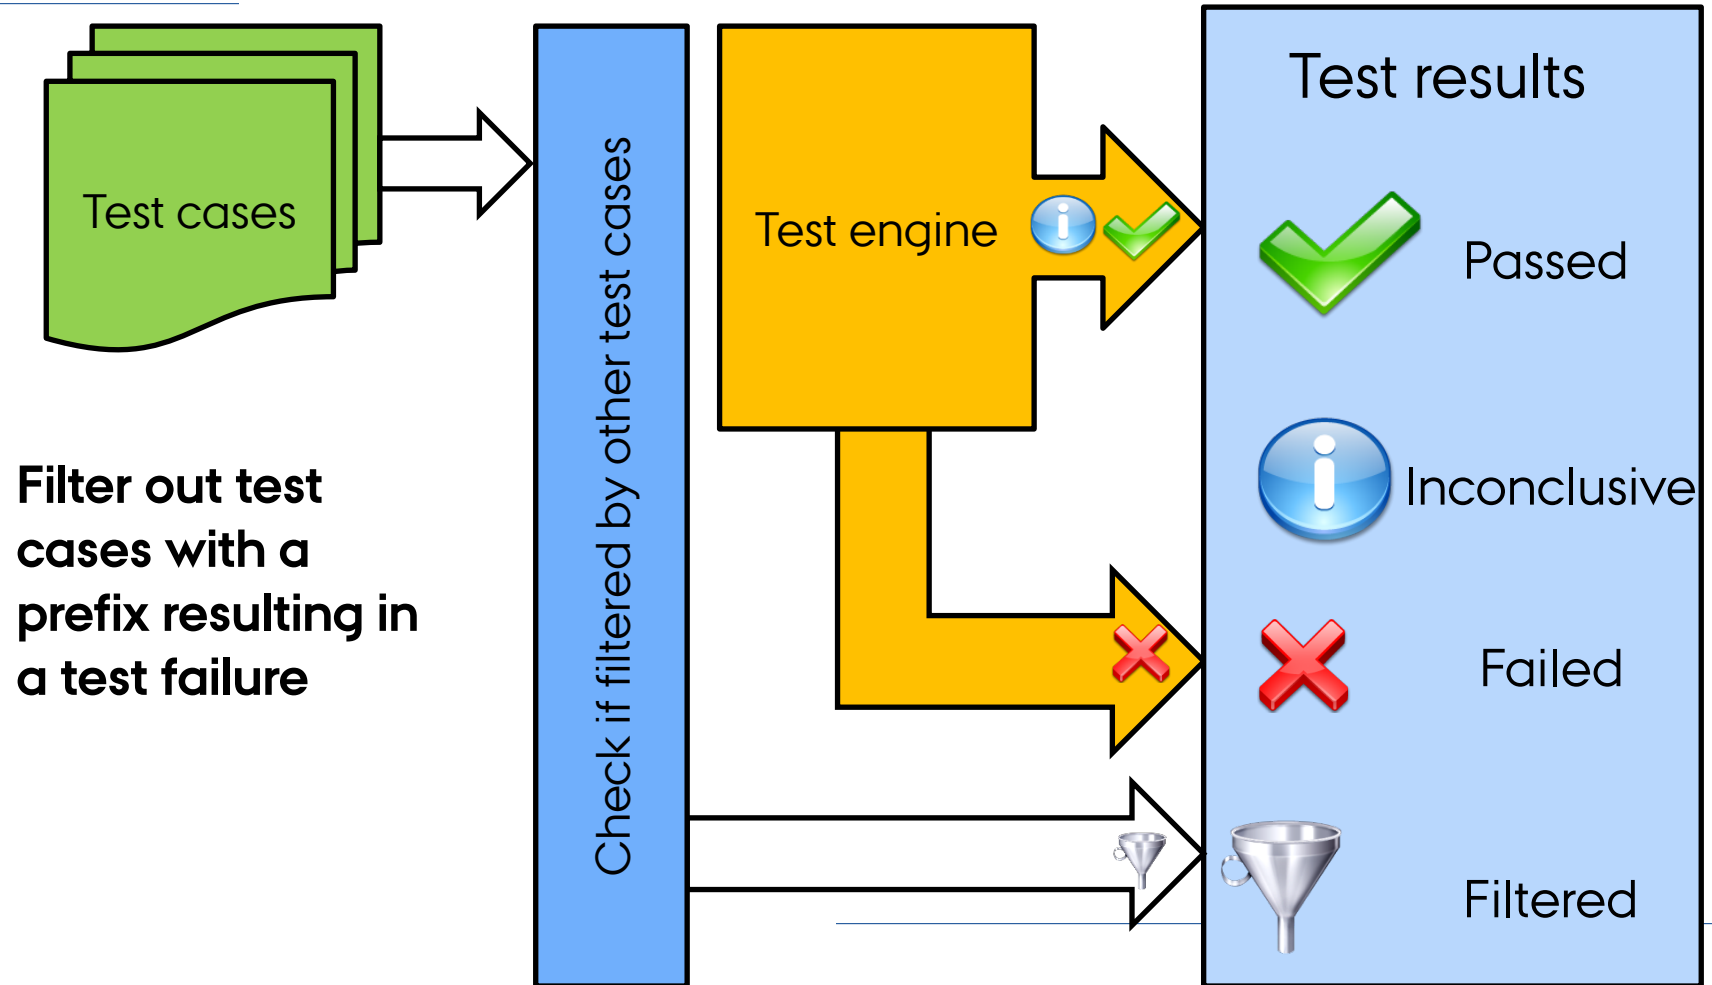

Generated Testcases:

```
TC1: t.Insert(1);t.Insert(1);t.Insert(1)  
TC2: t.Insert(1);t.Insert(1);t.Insert(2)  
TC3: t.Insert(1);t.Insert(2);t.Insert(1)  
TC4: t.Insert(1);t.Insert(2);t.Insert(2)  
TC5: t.Insert(2);t.Insert(1);t.Insert(1)  
TC6: t.Insert(2);t.Insert(1);t.Insert(2)  
TC7: t.Insert(2);t.Insert(2);t.Insert(1)  
TC8: t.Insert(2);t.Insert(2);t.Insert(2)
```

COMBINATORIAL TESTING OVERVIEW

TEST CASE EXECUTION

AN EXAMPLE

operations

public insert : **int** ==> ()
insert(val) == **skip**
pre val > 1;

traces

T1 : **let** x **in set** {1,2} **in** insert(x);

ANOTHER EXAMPLE

class A

values

obj : A = new A();

operations

public op : nat ==> nat

op (x) == return x;

traces

T2:

let x,y in set {1, ..., 10}

in

(obj.op(x);obj.op(y));

end A

How many test
cases will this
generate?

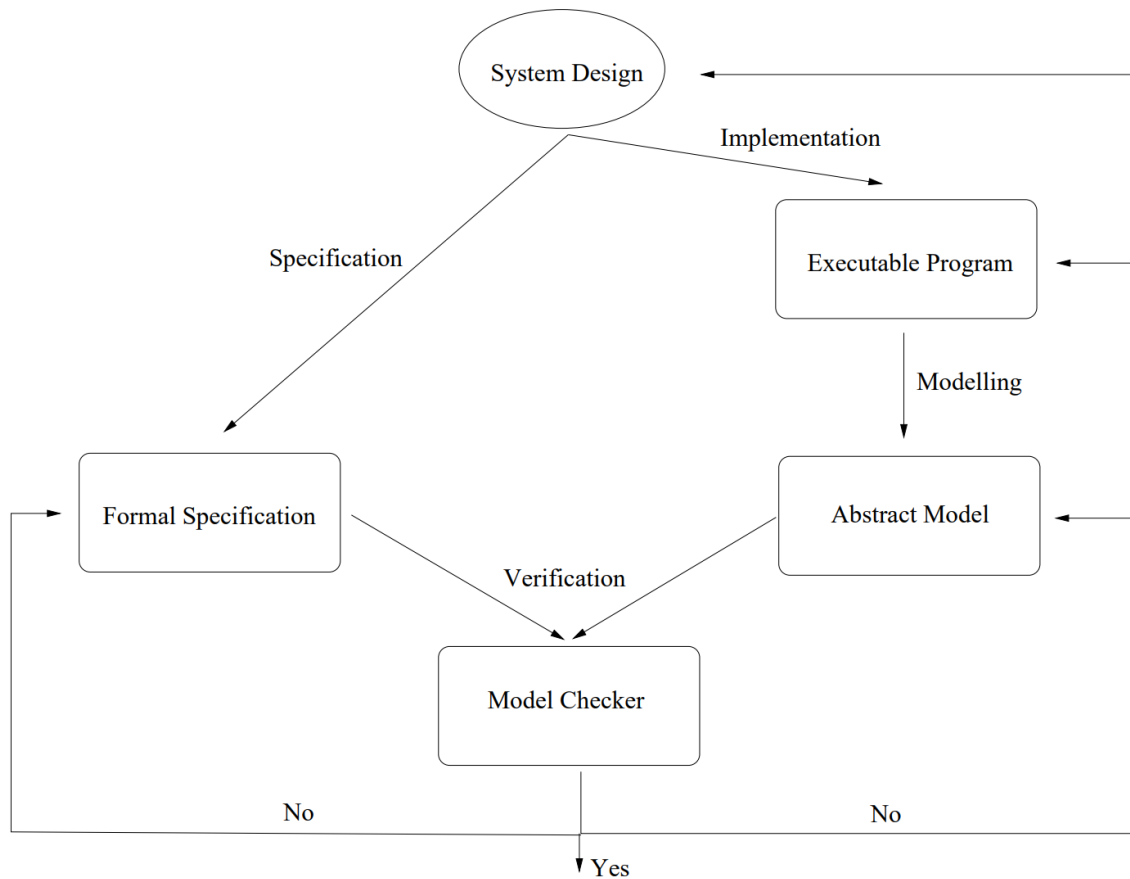

REGULAR EXPRESSIONS IN TRACES

- Let definitions (local naming)
- Let be such that definitions (all selection)
- Repeat traces (fixed or variable number of times)
- Concurrency traces (all interleavings)
- Application expression (calling operations)
- Trace alternatives

DESIGN SPACE EXPLORATION

MODEL CHECKING (1)

MODEL CHECKING (2)

- › Model checking is applicable for large systems, but with finite state space.
- › Constant and static state space.
- › Normally it uses an exhaustive search of the finite state space of the system.
- › Automatic exploration of the state space.

MODEL CHECKING (3)

- › Model specifies the system behavior in a formal way.
- › Properties:
 - › Safety: Invariants, deadlocks, reachability, etc
 - › Liveness: fairness, response, infinite traces, etc

SPECIFICATION/MODELING

› Description of the behavior of individual processes and potential synchronizations.

Example: 2 concurrent processes M1 and M2 competing for a semaphore S, each process has three states: Non-critical (N), Trying (T), Critical (C). Semaphore available (S_0) or taken (S_1).

$$\begin{array}{lcl}
 N_1 & \rightarrow & T_1 \\
 T_1 \wedge S_0 & \rightarrow & C_1 \wedge S_1 \\
 C_1 & \rightarrow & N_1 \wedge S_0
 \end{array}
 \quad \parallel \quad
 \begin{array}{lcl}
 N_2 & \rightarrow & T_2 \\
 T_2 \wedge S_0 & \rightarrow & C_2 \wedge S_1 \\
 C_2 & \rightarrow & N_2 \wedge S_0
 \end{array}$$

PROPERTIES DESCRIPTION

- › A property describes a requirement that **must always** be **satisfied** by the system execution, no matter how the system execution evolves.
- › Properties are usually described using a logic, or a syntax that is compatible with the specification language.

Example: process1 and process2 must **not** be in a **critical state** at the same time.

$$M1 \parallel M2 \models A[] \text{ not}(C_1 \wedge C_2)$$

- › Related to VDM syntax, a property can be: all invariants, pre-conditions and post-conditions must be satisfied.

VERIFICATION (1)

- › To check whether a property is satisfied or not, the model checker calculates first the **state space**.
- › State space is formed by **all potential executions**.
- › The verification visits each state in the statespace and checks whether the **property is satisfied** or not.
- › It terminates with **yes/no** (counterexample).

VERIFICATION (2)

Example: state space for $M1 \parallel M2$.

Property $M1 \parallel M2 \models \text{A}[] \text{ not}(C_1 \wedge C_2)$ is satisfied.

STATE SPACE EXPLOSION

- › The composition of two concurrent processes is modeled by taking the **Cartesian product** of the corresponding **state spaces**.
- › In general, $\text{state space} = [M_1] * [M_2] * .. * [M_n]$.
- › Even a small system (<10 proc) can end up in millions of states due to data/time variables.

Challenging drawback: state space **explosion**.

SYMBOLIC STATE SPACE

Two main approaches have been proposed to cope with the state explosion problem:

- › Symbolic algorithms.
- › Partial order reduction.

In symbolic model checking, logical formulas may be associated with the set of states that validate the formula. Thus compacting the state space.

SYMBOLIC ALGORITHMS

› Example: formula: $\text{inUse}(S) = y/n$ by one of the processes.

› State space can be reduced to $n/[p]$, n : original state space, p : number of processes.

SUMMARY

- › What have I presented today?
- › Combinatorial testing possibilities
- › Model checking and symbolic algorithms.
- › What do you need to do now?
- › Read chapter 13 for next week
- › Continue working on your mini-projects
